

Wallet Simulation

Rs5,000 swing plan - sweep vs compound, 4-year backtest. 8 Oct 2026.

Simulation of the live plan over the 4-year backtest: start Rs5,000, withdraw Rs3,000 every time equity reaches Rs10,000, using the live risk settings (1-3% risk per trade, 9% side-risk cap, 3x ATR / 3R / 7-day exits). All figures net of costs.

1. Headline result

Metric	Value
Starting capital	Rs5,000
Trades taken	808 (of ~3,430 signals - small balance skips many)
Win rate	48%
Avg per trade	+0.31 R
Total withdrawn	Rs27,000 (9 sweeps of Rs3,000)
Final balance	Rs7,056
Total value out	Rs34,056 (x6.8 on Rs5,000)
Times busted	0 (never)
Max drawdown	30%
First withdrawal	26 months in (Dec 2023)

Patience is the whole game: the first Rs3,000 sweep took 26 months. This is not a monthly-income plan.

2. Pure compounding (no withdrawals)

The same trades with profits left in to compound instead of being swept:

Path	Rs5,000 becomes	Multiple
Sweep plan (withdraw Rs3k @ Rs10k)	Rs34,056 total out	x6.8
Pure compound (no withdrawals)	Rs118,104	x23.6

Compounding beats the sweep plan ~3.5x over 4 years, but leaves all gains exposed the whole time. The sweep plan trades some upside for realised, banked profit and lower tail risk.

3. Sizing reality at small balance

- At Rs5,000 the 1-3% risk rule plus minimum lot sizes means ~80% of signals are skipped.
- Only the highest-conviction, cheapest-margin setups actually get taken (808 of 3,430).
- This is correct behaviour: forcing every signal at tiny size would just bleed fees.

4. Honest notes

- In-sample. The forward test will confirm or break these numbers.
- Assumes fills at backtest prices; live slippage on a real account will shave the edge.
- 30% max drawdown on Rs5,000 is Rs1,500 - survivable, but it will feel bad in the moment.
